

DAY-4

TASK 3: UNDERSTANDING LOGIC BEHIND CLOTHING RECOMMENDATION

A clothing recommendation system suggests outfits or clothing items to users based on their body measurements, preferences, and style patterns. The goal is to provide personalized fashion recommendations and improve the shopping experience in virtual try-on applications.

INPUTS WHICH ARE TAKEN TO GIVE RECOMMENDATIONS:

- Height
- Weight
- Body measurements
- Gender
- Preferred clothing style
- Color preference
- Occasion
- Browser History
- Similar users

The recommendation process begins with collecting user data, including height, weight, and preferred fashion style. The system then performs body measurement and size analysis to determine appropriate clothing fits. After this, similarity matching and filtering techniques are used to compare the user's preferences with available clothing options.

AI-based recommendation systems may also consider previous user interactions, trending fashion patterns, and similar customer behavior to generate more personalized suggestions. The final output provides customized outfit recommendations that improve shopping convenience and reduce size uncertainty.

This logic is highly important in virtual try-on systems because it helps users discover clothes that better match their body type and personal style, creating a more personalized and efficient online shopping experience.

HOW IT WORKS:

User Data

(Measurements, Browsing History and Fashion Interests)

Body Measurement Analysis

(Width, Height and Body Shape)

Preference Matching

(Compare with similar body types or fashion sense)

Size Matching

(Select perfect size for the customer)

Recommendation Engine

(Take all the data and use AI filtering systems to provide the best ones)

Personalized Clothing Suggestions

(Customer gets the suggestions and tells if he/she likes or dislike them so the AI suggestion system can improve)
